Abstract— The aim of this study was to evaluate the effects of different lysine levels on growth, carcass composition and immunological response to bird flu vaccination in Ac chicken. Four hundred fifty one-day-old chicks and two hundred forty of twenty eight-day-old chicken were arranged in a completely randomized design with 5 diets (different lysine contents of 0, 5, 10, 15 and 20% of the diet) and 3 replicates. Birds were fed ad libitum and had free access to water. Blood samples were collected to analyze immunological responses to H5N1 vaccination at 28 and 56 day-old. Six birds per a treatment were slaughtered to evaluate bodyweight, carcass composition and chemical composition. Results showed that feed consumption of birds was similar (99.2-111.9 g/bird/week) when increasing dietary lysine, but bodyweight gain and feed conversion ratio were improved (P<0.05) in diet with 10% lysine inclusion (52.4 g/bird/week and 2.09 kg feed/kg gain. respectively). In addition, bodyweight, carcass composition and amino acid content of breast muscle of Ac chicken were not different (P<0.05) between treatments, but ratio of weight of organs producing immunological antibodies of chicken was greater in the high lysine diets.

I. INTRODUCTION

Lysine is one of the limiting amino acids in broiler diets and it is used to calculate the remaining essential amino acids in the ration [3]. Lysine requirement of broilers is higher in low protein diets for maximum weight gain and feed efficiency [10]. As widely described, increasing dietary lysine generally results in improved feed intake, feed conversion ratio and body weight gain [22]. Moreover, lysine has impact not only on birds' growth but also on their ability against bird flu (H5N1) infection. Previously, [15] found that addition of lysine at high levels to the diets can stimulate insulin secretion from pancreas by aggregating in plasma, which in turn releases amino acid and fatty acids from the bodily saved sources and leads to protein synthesis.

Supportably, the report of [21] indicated that the addition and improvement of lysine in poultry diets improved birds' immune ability against different diseases.

In Vietnam, Ac chicken is an indigenous breed with black skin, meat and bones and is widely adopted in the Mekong Delta. Its meat quality is considered juicy with high levels of amino acids. Similar to other breeds, Ac chickens need amino acids for body growth and protein synthesis, of which lysine is the most important amino acid to concern. Previous work has focused on conservation [26], production [18] and protein and energy levels on performance and egg quality [17] but little was known on the effects of lysine inclusion levels on Ac chicken. This study was therefore designed to determine growth performance, carcass composition and immunological response to influenza vaccination in Ac chickens supplemented with lysine at different content in the diet.

II. MATERIALS AND METHODS

A. Experimental design and diets

The feeding experiment was allocated in a completely randomized design with 5 treatments and 3 replicates (thirty and sixteen birds for each treatment at 0-4 and 5-8 weeks of age, respectively). Vaccination against Newcastle disease was performed at the 5th day of age by nostril and eye drop method and bird flu at the 14th day of age by breast intramuscular injection. The diets were offered *ad libitum* and water was freely available throughout eight weeks. The experimental birds were fed with five diets including control (dietary lysine 1% and 0.9% of 0-4 and 5-8 week-old period, respectively) and other four diets were added with 5%, 10%, 15%, and 20% lysine as compared with the control diet. Details of nutritional values and composition of diets of two phases are shown in Table 1, Table 2 and Table 3, respectively.

B. Feed intake, body weight and carcass composition

Feed intake was recorded daily by weighing feed supply and refusal. Body weight was taken every week at 6 a.m. before chickens were fed. Feed conversion ratio was calculated as feed intake per unit of body weight. For carcass composition, 12 chickens (per treatment) were slaughtered at 8 weeks of age to determine the carcass, breast meat and leg meat ratios. Breast meat nutritional values (dry matter, crude protein, fat and ash content) were analyzed by Weende's proximate method [2] and amino acid composition was determined using the high-pressure liquid chromatography. Internal organs such as spleen, thymus and bursa of Fabricius were separared and weighed and the relative organ weight was calculated as percentage of body weight.

C. Antibody response analysis

A total of 6 blood samples in each treatment were collected from 6 birds via their hearts to determine maternal antibody levels against the bird flu disease. Determining antibody against the bird flu disease was done using haemagglutination method (HA) titration as suggested by [25].

D. Statistical analysis

Data on growth performance, bodyweight, carcass compositionand immunological responses were analyzed by one-way of variance (ANOVA) in [12]. The differences between experimental treatments were examined with Tukey's method.

III. RESULTS AND DISCUSSION

A. Growth performance and feed utilization

Body weight gain (BWG) and feed conversion ratio (FCR) of birds were significantly influenced (*P*<0.05) by the different diets (Table 4), of which BWG was highest in the Ctrl+10 (52.4 g/bird/week) but was lowest in Ctrl (43.62 g/bird/week) diet. Similarly, the feed conversion of birds was most efficient in Ctrl+10 (2.09 kg feed/kg weight gain), compared with other treatments. However, there was no significant difference regarding to feed intake of chickens among treatments. The present results partly supported the observations of [11] and [6] that lysine supplementation above NRC requirement [16] in broiler diets improved final body weight, total weight gain and feed intake.

Website: www.ijetae.com (ISSN 2250-2459, ISO 9001:2008 Certified Journal, Volume 7, Issue 7, July 2017)

Previously, the finding of [14] also identified a positive linearity of the relationship between lysine requirement and dietary protein level, which supported the view that lysine requirement for maximum productivity (maximum weight gain and feed efficiency) was in the range of 1.26 to 1.33% and this was above the NRC requirement of 1%. Moreover, [5] found that lysine supplementation significantly improved the live body weight and feed conversion efficiency. Supportably, [27] pointed out that the poor live weight performance of broilers fed with basal diets and the responses to supplemental L-lysine indicated that the basal diets were severely deficient in lysine. From the present work, it was also indicated that supplementary levels more than NRC requirement (>5%) was appropriate for enhancing growth rate of Ac chicken. This could be explained by the balance of amino acid content in the diets, where lysine is the basic unit to synthesize protein, it affects directly protein synthesis in the body of birds, and thereby improved growth rate of birds.

The composition of carcass and nutritional value of breast muscle of Ac chicken was not different among diets (P>0.05) (Table 5 and Table 6). The present output agreed with the finding of [23], which stated that carcass weight and breast muscle yield were not affected by dietary lysine. [20] also reported that lysine had no effects on breast and leg muscle weight. In contrast, [13] and [1] presented that breast meat yield reduced significantly from 1.05% to 0.85% when lysine content was limited. Moreover, [24] and [19] showed that excessive lysine increased muscle weights and breast muscle weight. In term of nutritional value, dry matter and protein content of breast meat were similar to the report of [26]. The results were consistent with findings of [7], who concluded that crude protein and crude fat of thigh meat were not influenced by the replacement of duckweed for soybean and rice bran in chicken diet. Similar results were also found in amino acid composition, where no effect of lysine was observed.

C. Immunological responsesto influenza vaccination

Evidences in the report of [8] and [9] showed that a dietary deficiency of lysine limited the synthesis of proteins and the proliferation of lymphocytes, as well as impaired immunological responses in birds, resulting in increases in morbidity and mortality in response to infection. There were also findings stating that an inadequate intake of dietary lysine reduced antibody responses and cellmediated immunity in chickens [4]. In addition, lysine and methionine supplementation to the diet has improved the immunity of chickens against potential diseases [21]. In the present study, there was no significant difference on birds' spleen ratio between diets; however, Fabricius and thymus ratio of birds was statistically influenced (P < 0.05) by different amounts of dietary lysine (Table 7). In the Ctrl+20, Ctrl+15, and Ctrl+10, the ratios of Fabricius (0.146%, 0.141%, and 0.134%, respectively) and thymus (0.522%, 0.542%, and 0.536%, respectively) was higher than that of Ctrl with 0.104% of Fabricius and 0.382% of thymus.

As dietary lysine contents increased from 1% to 1.15% and from 0.9 to 1.03 in stages 0-4 and 5-8 weeks of age, respectively, the ratio of Fabricius and thymus gradually increased. Lysine is an essential amino acid that is necessary to produce proteins including antibodies; thus, adequate dietary levels of lysine isneeded to support optimum efficacy of the immune system. Although the value of log₂ HI titre of the Ctrl treatment tended to be lower than those of the other treatments, the antibody titre against avian influenza at 28 and 56 day-old were not significantly different among treatments. [11] reported that increased lysine content in diets of broilers in excess of NRC recommendation could improve immune system functions against Newcastle disease. Therefore, an appropriate vaccination regime should be taken into consideration for Ac chicken to fully achieve the efficacy of immune function.

IV. CONCLUSIONS

The present study demonstrated that dietary lysine supplementation at 10% improved growth performance and feed conversion ratio butcarcass composition were not influenced. The ratios of spleen and thymus were improved but immunological responses to influenza vaccination remained unchanged despite the increased lysine content in the diet.
